Subject: Response to United States Environmental Protection Agency Comments on
Methodology and Calculation of Alert Levels and Aquifer Quality Limit for
Groundwater Compliance Monitoring at the Florence Copper PTF Project Monitoring Wells

Dear Mr. Albright:

Per your request, we are submitting revised Alert Level and Aquifer Quality Limit calculations. The calculations for iron, manganese, gross beta, radon, total uranium, and nitrate as N have been revised to reflect the individual well calculations.

Please contact me at (520) 374-3984 should you have any questions regarding this response.

Sincerely,

Florence Copper Inc.

Procedures for Determining Alert Levels and Aquifer Quality Limits for Groundwater Compliance Monitoring

Florence Copper Project
Florence, Arizona

June 1, 2018

Revised December 12, 2018

2 North Central Avenue, Suite 1600
Phoenix, Arizona 85004

INTRODUCTION

Temporary Aquifer Protection Permit (APP) No. P-106360 and Underground Injection Control (UIC) Permit No. R9UIC-AZ3-FY11-1 require the calculation of alert levels (ALs) and aquifer quality limits (AQLs) for groundwater compliance monitoring at the Florence Copper Inc. facility (Facility).

The APP outlines methodology for calculating ALs, along with a set of criteria to follow for selecting the final AL and AQL in Permit Conditions 2.5.3.2.1 – Alert Levels for POC Wells, and 2.5.8.5.1 – Alert Levels for Supplemental Wells and MW-01. The majority of the ALs were set using the permit-described methodology. In cases where datasets have reduced variability, this document outlines modifications to the permit method which were used to calculate the ALs and AQLs.

In November 2018, the document was revised to address comments by the United States Environmental Protection Agency (USEPA). The following items were revised:

- Table 4b was revised to include AQLs for the UIC Permit, which differ slightly from those required by the APP;
- The proposed k value was lowered from 9.37 to 7.47;
- Individual ALs and AQLs were generated for field pH, gross/adjusted alpha, and radium 226+228; and
- Two additional results were excluded as outliers.

In December 2018, the document was revised to address a request by the USEPA. The following items were revised:

- Individual ALs and AQLs were generated for iron, manganese, gross beta, radon, total uranium, and nitrate.

PERMIT METHODOLOGY

The Temporary APP outlines the methodology for setting ALs and AQL. There are three general steps:

- Data preparation;
- Using the mean and standard deviation to calculate a statistical AL; and
- Using case criteria to determine the final ALs and AQLs.

DATA PREPARATION

Permit Methodology

Data was prepared for AL calculations as outlined in the Temporary APP.

- ALs are calculated using a minimum of 8 and a maximum of 12 consecutive sample rounds.
 - In the majority of cases, 9 sample results are used; except where an outlier is identified.
- Any data where the laboratory practical quantitation limit (PQL) exceeds 80% of the Aquifer Water Quality Standard (AWQS) have been excluded from the calculations.

Brown & Caldwell

- Four aluminum and four iron results were excluded from the calculations.
- Obvious outliers are excluded from the calculations.
 - Outliers were determined primarily on the basis of graphical review.
 - The total dissolved solid (TDS) results for M54-LBF and M54-O from August 15, 2018 were likely switched. These outliers were excluded.
 - The iron result for M56-LBF on July 17, 2017 was excluded.
 - The zinc result for MW-01-LBF on February 8, 2018 was excluded.
 - The radon results for M52-UBF, M59-O, M60-O, and M61-LBF on July 19, 2017 were excluded.
 - The radon result for M55-UBF on October 25, 2017 was excluded.
 - The radon results for M57-O and M58-O on March 6, 2018 were excluded.

In addition:

- Duplicate analytical results were removed.

Handling of Non-Detect Values

The APP prescribes using a value of one-half of the PQL for results below the detection limit for the calculation of ALs.

For cases where a dataset contains at least one non-detect but less than 50% of the results are non-detect, the statistical method proposed below accommodates the non-detects, which only need to be identified at the value of the PQL.

For cases where greater than 50% of the results are non-detect, in the majority of cases, the AL is set by permit to 80% of the standard. While an Upper Protection Limit (UPL) could be calculated, it is not necessary and, therefore, replacement of the non-detect with one-half the PQL does not affect the permit-derived AL. Special cases are discussed in greater detail below.

ALERT LEVEL CALCULATIONS

Permit Methodology

The permit prescribes calculation of the ALs based on a tolerance interval. The AL is calculated with the following equation:

$$AL = \bar{x} + k \cdot s$$

where:

\bar{x} = the mean of the existing concentrations in a given well;

s = the standard deviation of the existing concentrations in a given well; and

k = a multiplicative factor that accounts for uncertainty in the analysis and the desired coverage and confidence of the AL (discussed below).

The values of \bar{x} and s are calculated from the existing concentrations using appropriate statistical methods.

Note that for field pH, which has both upper and lower AL, a lower AL is calculated as $\bar{x} - k \cdot s$.

Development of the *k* Constant

The permit recommends using the Lieberman Tables for a one-side normal tolerance interval with a 95% confidence level. Based on a 99% coverage and a sample size of 9, the *k* value for this data set would be 4.143.

In reviewing preliminary calculations, it was observed that many of the datasets have low-variability, resulting in ALs that would only marginally exceed the maximum observed value.

Table 1A – Example Case 1 shows the calculation of the AL for a magnesium dataset with no non-detect values:

Average – 9.1

Maximum – 11

Standard Deviation – 1.13

$$\text{Calculated UPL} = 9.1 + 1.13 * 4.143 = 13.8$$

Because the calculated AL is only marginally higher than the maximum observed value, it is likely that a result may exceed the calculated AL due to natural water-quality variation. The 99% coverage of the AL means that the AL represents the 99th percentile of the dataset, which would be exceeded approximately 1% of the time, even under natural conditions. Based on the number of wells and analysis required for the project, this could translate to as many as 10 false positives in a year.

Modified *k* Value – Upper Prediction Limit

An alternative statistical method for calculating the *k* value is described by the United States Environmental Protection Agency (EPA) in “Statistical Analysis of Groundwater Monitoring Data at RCRA Facilities – Unified Guidance” (EPA, 2009). The AL calculated is a UPL, representing a value that is unlikely to be exceeded by any single future measurement, unless groundwater conditions have changed. The value of *k* is calculated as:

$$k = t_{1-\alpha, n-1} \cdot \sqrt{1 + \frac{1}{n}}$$

where:

n = the sample size of the existing concentration dataset for a given well;

α = the desired false positive rate of the UPL (discussed below); and

$t_{1-\alpha, n-1}$ = the value of the t-distribution for the given values of *n* and α .

Because the dataset of existing concentrations represents only a sample of the full range of possible concentrations, the chance that the UPL will be exceeded even in the absence of a release to groundwater cannot be reduced to zero. The chance that the UPL will be exceeded in the absence of a release to groundwater is managed through the chosen value for α .

An exceedance of a UPL, even in the absence of a release to groundwater, is called a “false positive.” The expected rate of occurrence of false positives (i.e., the false positive rate) is controlled through the value of α . α is equal to the desired false positive rate, and thus a value

of $\alpha = 0.01$ would indicate that the UPL has a 1% chance of being exceeded every time a new sample is collected, even if a release to groundwater has not occurred.

Future groundwater samples will be compared to ALs and AQLs for many parameters in many wells multiple times per year. Even if every UPL had only a 1% chance of recording a false positive during each comparison to a new data point, the chance of observing at least one false positive throughout the year would be unacceptably high. To avoid this problem, the false positive rate of each UPL is set at a sufficiently small value to ensure that the overall false positive rate over the course of the year (called the cumulative false positive rate) is reasonably small.

The value of α for each UPL is determined from the desired cumulative false positive rate using the following equation (EPA, 2009):

$$\alpha = 1 - (1 - \alpha_c)^{1/N_T}$$

where:

α_c = the desired cumulative false positive rate; and

N_T = the number of tests (i.e., comparisons to a UPL) conducted over the course of a year.

The number of comparisons to a UPL per year is determined from the number of parameters, number of wells, and sampling frequency. For the APP:

- Four parameters (the common ions) are sampled four times per year.
- A full set of additional parameters (23 parameters in total) is sampled twice per year.
- The number of wells that are to be sampled each year include:
 - the 3 new point-of-compliance (POC) wells;
 - 9 supplemental wells; and
 - plus 4 existing POC wells that already have established ALs and AQLs.
- Thus, the total number of comparisons per year is 992 (Table 2).

The cumulative false positive rate is chosen to minimize, to the degree possible, the chances of observing at least one false positive in a given year. The trade-off to choosing a low cumulative false positive rate is that the value of k , and thus the UPLs, increase and are less sensitive to detecting releases to groundwater. However, given the nature of the mining solutions, a release to groundwater would be expected to produce a significant change in groundwater chemistry, quickly exceeding the ALs. Thus, minimizing false positives can be achieved without limiting the effectiveness of the groundwater monitoring program.

The value of the cumulative false positive rate originally selected in this analysis was 0.01. This means that there would have been approximately a 1% chance of observing at least one false positive every year, provided that groundwater conditions do not change (either due to a release or through natural variation). In other words, false positives would have been expected to occur with a frequency of one every 100 years, assuming stable groundwater conditions. For this revision, this false positive rate has been increased to 0.05, or a 5% chance of observing a false positive in order to provide a more conservative k value below.

The cumulative false positive rate of 0.05 gives a value of α for each UPL of 5.17×10^{-5} , which gives a value for k of 7.47 when the sample size of the dataset is 9. Although the k value would be higher for any data set with 8 samples, i.e. where an outlier has been excluded, for the purposes of these calculations, the same k value of 7.47 will be used for consistency, since this is a more conservative result.

Using this proposed k value for the example case yields a UPL that is less likely to have false positives but is nonetheless protective of groundwater.

For Example Case 1:

Average – 9.1

Maximum – 11

Standard Deviation – 1.13

Calculated UPL = $9.1 + 1.13 * 7.47 = 17.6$

Note that while the UIC has some additional parameters, and thus a higher number of comparisons (N_T) which would result in a higher k value, the standard k value of 7.47 is used for consistency throughout.

Adjusted Standard Deviation

In some cases, the datasets have extremely low variability. This is not unexpected because the data were collected over a relatively short period of time and may not reflect long-term variability in groundwater conditions. Table 1B – Example Case 2 demonstrates the potential for a UPL, using the revised k value, that is still likely to result in false positives:

Average – 23.3

Maximum – 24

Standard Deviation – 0.5

Calculated UPL = $23.3 + 0.5 * 7.47 = 27.1$

A water-quality variation of less than 12% would yield an exceedance.

To account for the low variability, an adjusted standard deviation is used:

- The coefficient of variation (CV) is calculated for each dataset where:
 - CV = standard deviation divided by the mean.
- For datasets with a CV less than 0.1; the standard deviation is set to 10% of the mean.

The CV is a standardized measure of variability. In other words, the CV for a dataset with a mean of 1,000 can be directly compared with the CV for a dataset with a mean of 10. The same cannot be said for the standard deviation, which is dependent on the magnitude of the data points as well as the variability.

For-Example Case 2:

Average – 23.3

Maximum – 24

Standard Deviation – 0.5

Coefficient of Variation = 0.02, below 0.1

Adjusted Standard Deviation = 10% of Average = 2.3

Calculated UPL = $23.3 + 2.3 * 7.47 = 41$

This yields a UPL that is similar in relative magnitude to the dataset in Example Case 1 and less prone to false positives.

Note that the CV adjustment is not used for field pH. Because pH is calculated as the negative logarithm of hydrogen ion concentrations, it is inherently less variable than other parameters. Applying the adjustment when the CV is below 0.1 would have resulted in pH UPLs greater than 14 or lower prediction limits (LPLs) less than 1. Exempting field pH from the adjustment results in more realistic UPLs and LPLs.

Datasets with Non-Detects

For datasets with all detected results, the mean and standard deviation are calculated using standard methods (e.g., arithmetic average and sample standard deviation formulas found in software such as Microsoft Excel).

If a dataset contains at least one non-detect but the percentage of non-detects is less than 50%, it is proposed to calculate the mean and standard deviation using the Kaplan-Meier Method, as recommended by Helsel (2005). All calculations will be performed in Microsoft Excel, the R Statistical Programming Language (R Core Team, 2016), or the EPA's ProUCL software, version 5.1 (EPA, 2015).

For cases where greater than 50% of the results are non-detect, in the majority of cases, the AL is set by permit at 80% of the standard. While a UPL could be calculated, it is not necessary and, therefore, replacement of the non-detect with one-half the PQL does not affect the permit-derived AL. Parameters with large numbers of non-detects include fluoride, several trace metals, organics, and radium.

In the case of cobalt, there is no established standard for calculation of an AL. The permit-recommended method was used to replace the non-detect values with one-half of the PQL. An adjusted standard deviation was used to generate the UPL.

For naphthalene, octane, and total petroleum diesel hydrocarbons (TPH-D), each of the data sets contain 100% non-detected results and there are no established standards. In these cases, the full PQL was used to generate an average and an adjusted standard deviation.

Examples of the four types of non-detect datasets are shown in Table 1C – Example Case 3. While these last two approaches are not ideal, they provide a method to generate a UPL where no standard exists.

UPLs by Well vs by Parameter

Four parameters have been selected in the Temporary APP and UIC as primary indicator parameters. Individual UPLs were calculated for these on a well-by-well basis.

For most trace metals and organics where there is limited variability, low concentrations relative to the standard, or a large number of non-detects, the entire data set for all wells was used to calculate a UPL.

If sufficient variability existed over the set of wells, then individual UPLs were calculated.

ALS AND AQLS FOR PARAMETERS WITH AWQS

Once a UPL was calculated, it was compared to the numerical AWQS to determine the final AL and AQL in accordance with the permit. Table 3 outlines the case criteria described in the permit. Table 4a gives a summary of all the ALs and AQLs calculated and includes the method used to set the final AL for each parameter for the APP, while Table 4b summarizes the UIC values and highlights where there are differences in the two tables.

Permit Methodology

Numerical AWQS have been established for fluoride, 11 trace metals, benzene, toluene, ethylbenzene, xylene (BTEX), alpha, and radium. For each parameter with an AWQS, the ALs and AQLs was set as follows:

Case 1 – POC Wells

- If greater than 50% of the results for a well are non-detect, then the AL is set at 80% of the AWQS and the AQL is set equal to the AWQS;
- If the calculated UPL is less than 80% of the AWQS, then the AL is set at 80% of the AWQS and the AQL is set equal to the AWQS;
- If the calculated UPL is greater than 80% of the AWQS but less than the AWQS, then the AL is set equal to the UPL and the AQL is set equal to the AWQS; and
- If the calculated UPL is greater than the AWQS, then the AQL is set equal to the calculated UPL. No APP-AL is set for that parameter at that monitoring point, and the UIC-AL is set equal to the UPL.

Case 2 – Supplemental Wells

- If greater than 50% of the results for a well are non-detect, then the AL is set at 80% of the AWQS, and the UIC AQL is set equal to the AWQS;
- If the calculated UPL is less than 80% of the AWQS, then the AL is set at 80% of the AWQS, and the UIC AQL is set equal to the AWQS;
- If the calculated UPL is greater than 80% the AWQS but less than the AWQS, then the AL is set equal to the calculated UPL value and the UIC-AQL is set equal to the UPL; and
- APP AQLs are not required for supplemental wells.

Note that, although nitrate and nitrite have AWQS, the Temporary APP states that ALs and AQLs are not required, as they are not parameters of concern for the process. However, ALs and AQLs are calculated for both compounds for the UIC Permit.

ALS FOR INDICATOR PARAMETERS

Indicators with Secondary Standards

Indicator parameters do not have an established AWQS. Secondary drinking water standards (SDWS) are available for sulfate, total dissolved solids (TDS), and five trace metals. For each parameter with an SDWS, it is proposed to set ALs and AQLs using the same methodology described above.

- If greater than 50% of the results for a well are non-detect, then the AL is set at 80% of the SDWS, and the UIC AQL is set equal to the SDWS;
- If the calculated UPL is less than 80% of the SDWS, then the AL is set at 80% of the SDWS, and the UIC AQL is set equal to the SDWS; and
- If the calculated AL is greater than 80% the SDWS, then the AL is set equal to the calculated UPL value and the UIC-AQL is set equal to the UPL.

Indicators with No Secondary Standard

Parameters magnesium, cobalt, naphthalene, octane, TPH-D, radon, and total uranium do not have an AWQS or SDWS.

- The AL for magnesium is set to the calculated UPL for each well;
- The AL for cobalt is set to the calculated UPL based on all 12 wells;
- Naphthalene, octane, and TPH-D are set to the calculated UPL based on all 12 wells; and
- For the radon and total uranium, the AL is set to the calculated UPL for each well.

APP AQLs are not required for parameters that do not have an established AWQS. The UIC Permit requires some parameters to have AQLs which are set equal to the AL.

CALCULATION TABLES

Table 4 provides a summary of the proposed AL and AQLs. Support calculations are provided in Tables 5-9.

- Table 5 – Primary Four Indicator Parameters (Level 1)
- Table 6a – Trace Metal Parameters Calculated by Parameter
- Table 6b – Trace Metal Parameters Calculated by Well
- Table 7 – Organic Parameters
- Table 8a – Radiochemical Parameters
- Table 8b – Additional UIC Radiochemical Parameters
- Table 9 – Additional UIC Common Ions

FIELD AND LABORATORY DOCUMENTS

Groundwater sampling and analysis was conducted in accordance with the requirements of APP Section 2.5.3 (Groundwater Monitoring and Sampling Protocols). Sampling, preservation, and holding times were in accordance with accepted industry standards. Field summaries for each monthly event include the field sheets, calibration records, daily notes, and deviations from standard sampling protocols. The field summaries and laboratory reports are included as Attachment 1 on CD.

TABLE 4a - SUMMARY OF ALERT LEVEL AND AQUIFER QUALITY LEVEL VALUES FOR THE APP

Notes:

¹Arsenic AL set to 0.026 mg/L for select pre-existing wells by permit. This value is below the standard AL of 0.04 mg/L. The lower value is proposed for all wells for consistency.

²The AWQS applies to Adjusted Alpha which equals Gross Alpha minus Uranium Isotopes. Adjusted Alpha is calculated if Gross Alpha is greater than 12 picocuries per liter, otherwise Gross Alpha is used.

³All wells calculated by standard AL method with one exception where results were significantly different from the average to warrant a separate AL.

⁴Beta speciations are performed above 50 pCi/L. All ambient results were below the speciation level.

Total Uranium (UIC)	Well by Well	NE	NE	0.0081	NA	0.0118</																							

Notes:

¹Arsenic AL set to 0.026 mg/L for select pre-existing wells by permit. This value is below the standard AL of 0.04 mg/L. The lower value is proposed for all wells for consistency.

²The AWQS applies to Adjusted Alpha which equals Gross Alpha minus Uranium Isotopes. Adjusted Alpha is calculated if Gross Alpha is greater than 12 picocuries per liter, otherwise Gross Alpha is used.

³All wells calculated by standard AL method with one exception where results were significantly different from the average to warrant a separate AL.

⁴Beta speciations are performed above 50 pCi/L. All ambient results were below the speciation level.

Highlights indicate where the UIC requirements for establishing AOLs are different from the APP requirements.

Notes:

All results in milligrams per liter (mg/L).

(#) = Outlier or RL above 80% of standard, excluded from calculations.

Red = Values are non-detected at the PQL shown.

Italics = Values are non-detected. One-half the PQL shown.

Blue = Coefficient of Variation <0.1

AL = Alert Level

AQL = Aquifer Quality Limit

AWQS = Aquifer Water Quality Standard

NA = Not Applicable

Arsenic AL set to 0.026 mg/L for select wells by permit. Used for all wells for consistency.

NE = Not Established

SDWS = Secondary Drinking Water Standard

UPL = Upper Prediction Limit

Notes:

All results in milligrams per liter (mg/L).

AL = Alert Level

NA = Not Applicable

Red = Values are non-detected at the PQL shown.

AQL = Aquifer Quality Limit

NE = Not Established

* = UIC Permit Limits

AWQS = Aquifer Water Quality Standard

PQL = Practical Quantitation Limit

(#) = Outlier excluded from calculations.

TPH = Total Petroleum Hydrocarbons

Notes:

All results in milligrams per kilometer (mg/L).

(#) = Outlier, excluded from calculations.

The Gross Alpha or Adjusted Alpha, if calculated, is shown.

Red = Values are non-detected at the PQL shown.

Blue = Coefficient of Variation <0.1

Results shown as the primary result and the radioactivity range is not shown.

AL = Alert Level

AQL = Aquifer Quality Limit

AWQS = Aquifer Water Quality Standard

NA = Not Applicable

NE = Not Established

UPL = Upper Prediction Limit
